```
I. vim /etc/yum.repos.d/rhce.repo
    [RHCE RHEL7]
    name=RHCE RHEL7
   baseurl=http://.../...
    enabled=1
    gpgcheck=0
   yum repolist
II.
     a/ allow SSH for xyz.com and deny SSH to all the others:
               vim /etc/hosts.allow -> sshd: .xyz.com
               vim /etc/hosts.deny -> sshd: ALL
     b/ allow SSH for only specific IP and block all the others:
               vim /etc/hosts.deny -> sshd: ALL EXCEPT 192.168.0.1
     c/ denies all services to all hosts unless permitted in hosts.allow:
           vim /etc/hosts.allow -> ALL: .foobar.edu EXCEPT terminalserver.foobar.edu
           vim /etc/hosts.deny -> ALL
     d/ access granted by default, redundant file hosts.allow
           vim /etc/hosts.deny -> some.host.name, .some.domain
           vim /etc/hosts.deny -> ALL EXCEPT in.fingerd: other.host.name, .other.domain
     e/ rules can be also only in one file, for example:
           vim /etc/hosts.allow -> ALL: .friendly.domain: ALLOW
                                   ALL: ALL: DENY
           vim /etc/hosts.allow -> ALL: .bad.domain: DENY
                                   ALL: ALL: ALLOW
III. Recover root passwd: reboot;e;linux16...rd.break;ctrl+x;mount -oremount,rw /sysroot;
     chroot /sysroot;passwd root;touch /.autorelable;exit;exit;

      /myshare 172.25.0.0/16
      /myshare 172.25.11.10(rw,no root squash) *.example.com(ro)
     no root squash=by default, root on a NFS client is treated as user nfsnobody by the
NFS server. That is, if root attempts to access a file on a mounted export, the server will
treat it as an access by user nfsnobody instead. This is a security measure that can be
problematic in scenarios where the NFS export is used as "/" by diskless clients and root
needs to be treated as root.

     AuthType basic (-set basic authentication)
     AuthName "This site is protected. Enter password:"
     AuthUserFile /etc/httpd/conf/userpasswords (specifies the file with user/passwd)
     Require user user1 (-or simply valid-user for anyone in the userpasswords file)
</Directory>
htpasswd -bc /etc/httpd/conf/userpasswords user1 p4ssw0rd
chmod 0640 /etc/httpd/conf/userpasswords
chgrp apache /etc/httpd/conf/userpasswords
```

(-together with AuthUserFile, you can use AuthGroupFile and Require group. Content of the group file is: cat /etc/httpd/conf/grouppasswords: groupname: user1 user2 user3. These users must be in userpasswords file) c/ Virtual hosts vim /etc/httpd/conf.d/00-site1.conf <Directory /srv/site1/www> (-this block provides access to document root further down) Require all granted AllowOverride none </Directory> (-this block must be considered for all connections <VirtualHost 192.168.0.1:80> on 192.168.0.1:80, can be _default_:80 or *:80 which will ALWAYS match for regular http traffic, effectively disabling the main server config from ever being used on port 80) DocumentRoot /srv/site1/www (-only applies for within this virtual host) ServerName site1.example.com[:80] (-name-based virtual hosting, if multiple virtual hosts are defined, the one where hostname matches this will be used, it is best to always explicitly use this. It doesn't need to exist, if you need "match anything" - e.g. all other domains types of VirtualHosts) (-if the virtual host needs to be used for more ServerAlias site1 than one domain name, wildcards can be used e.g. *.example.com) ServerAdmin root@site1.example.com ErrorLog "logs/site1 error log" CustomLog "logs/site1 access log" combined </VirtualHost> httpd -D DUMP VHOSTS If there are multiple catch-all VirtualHosts, they will be executed alphabetically (e.g.00default.conf, default.conf, vhost.conf) (-How the server selects the proper name-based virtual host? When a request arrives, the server will find the most specific virtual host argument based on IP/port used by the request. If there is more than one containing the best-match, Apache will further compare the ServerName and ServerAlias directives to the server name present in the request. If no matching ServerName/ServerAlias is found in the set of virtual hosts, then the first listed virtual host that matches will be used.) (-Any request that does not match existing virtual host is handled by the global server configuration /etc/httpd/conf/httpd.conf, regardless of hostname/ServerName. When you add virtual host to an existing server and the virtual host match preexisting IP/port, request will now be handled virtual host. In this case, it is wise to create default virtual host with ServerName matching the base server.) c/ Access control directives: <RequireAll></RequireAll> - none must fail and at least one must succeed <RequireAny></RequireAny> - one or more must succeed <RequireNone></RequireNone> - none must succeed If it is not enclosed in directives, it is automatically <RequireAny> I. <RequireAll> Require all granted Require not ip 10.252.46.125 (-address is an IP, partial IP, network/mask, network/CIDR, ipv4/ipv6) </RequireAll> II. <RequireAll> Require all granted Require not ip 192.168.2.1 Require not host phishers.example.com moreidiots.example (-address is FQDN or part of it, multiple may be provided) Require not host gov </RequireAll> III. Require all denied Require local

IV. Require host test.example.com (-to only allow specific hostname)

V. Require user john (-can be username/UID)

VI. Require not user badjohn (-can be groupname/GID)
